3 **ELECTRONIC DEVICE WORKPIECE PROCESSING APPARATUS**
4 **INSAI**
5 **TECHNICAL FIELD**

6 The present invention relates to an electronic device workpiece
7 processing apparatus and method of communicating signals within an
8 electronic device workpiece processing apparatus.

9 **BACKGROUND OF THE INVENTION**

10 It is preferred in the semiconductor and related arts to utilize
11 large wafers for fabrication of integrated circuits and other devices.
12 Large wafers are preferred inasmuch as an increased number of chips
13 can be fabricated from larger workpieces. As the size of the wafers
14 continues to increase as processing techniques are improved, additional
15 processing obstacles are presented.

16 For example, it is typically preferred to provide a substantially
17 uniform temperature across the surface of wafers being processed
18 because changes in temperature can influence device fabrication. Wafers
19 of increased diameters and surface areas experience increased
20 temperature fluctuations at various locations on the workpiece. In
21 particular, a partial vacuum is typically used to pull small diameter
22 wafers into direct thermal contact with a hot plate. Such processing
23 methods facilitate substrate temperature control because the substrate
24 temperature is closely associated to the temperature of the hot plate.
25 Fabrication of small sub-micron devices upon larger diameter

1 semiconductor wafers or workpieces requires minimal backside
2 contamination. As such, contact of the workpiece with the hot plate
3 is not typically possible. Large workpieces are processed in conventional
4 operations upon spacers or pins that position the workpiece
5 approximately 0.1 millimeters above the hot plate surface. Such spacing
6 intermediate a chuck or hot plate and the workpiece can result in
7 temperature fluctuations across the surface of the workpiece.

8 The utilization of specific materials for processing large workpieces
9 in small geometry applications presents numerous obstacles. Absolute
10 workpiece temperature and workpiece temperature uniformity are
11 parameters which are closely monitored during wafer and workpiece
12 fabrication to provide critical dimension (CD) control. Chemically
13 amplified resists are often utilized in deep ultraviolet (DUV) lithography
14 in small micron geometries (eg., 0.25 microns and below). Chemically
15 amplified resists are particularly temperature dependent further increasing
16 the importance of temperature control and monitoring. Some thermal
17 resist processing steps require process windows ranging from 1-2 degrees
18 centigrade down to a few tenths of a degree centigrade. Meteorology
19 that is four to ten times more precise than conventional process
20 equipment is typically utilized to provide thermal performance
21 measurements to 0.1 degrees centigrade.

22 One approach has disclosed the use of temperature sensors across
23 a surface of the wafer to provide temperature mapping of the
24 workpiece during processing. Platinum foil and copper leads are utilized

1 to electrically connect the temperature sensors. With the use of
2 numerous temperature sensors across an entire workpiece surface,
3 numerous wires are required for coupling and monitoring. Such
4 numerous wired connections can break and/or adversely impact
5 processing of the workpiece or the temperature measurements taken of
6 the surface of the workpiece. Some temperature sensors require four
7 leads per sensor further impacting the processing and temperature
8 monitoring of the workpieces.

9 An improved method of providing temperature information is
10 disclosed in U.S. Patent Application Serial No. 09/032,184, entitled
11 "Electronic Device Workpieces, Methods of Semiconductor Processing and
12 Methods of Sensing Temperature of an Electronic Device Workpiece",
13 filed February 27, 1998, naming Dr. Salman Akram and David R.
14 Hembree as inventors, assigned to the assignee hereof, and incorporated
15 herein by reference.

16 There exists a need to provide additional improvements for
17 monitoring of processing of workpieces.
18

19 SUMMARY OF THE INVENTION

20 The invention provides electronic device workpiece processing
21 apparatuses, and methods of communicating signals within an electronic
22 device workpiece processing apparatus. Exemplary electronic device
23 workpieces include production workpieces (e.g., silicon wafers) and
24 calibration wafers.

1 One aspect of the invention provides an electronic device
2 workpiece processing apparatus including a chuck, intermediate member
3 and an electronic device workpiece. The chuck includes an electrical
4 interconnect configured to conduct signals within the chuck. The
5 intermediate member is configured to conduct signals intermediate
6 opposing surfaces of the intermediate member. The electronic device
7 workpiece includes one or more sensors. An exemplary sensor
8 comprises a resistance temperature device (RTD) configured to provide
9 process signals containing process information regarding the electronic
10 device workpiece processing apparatus. A data gathering device or
11 recorder can be provided to record process information generated by the
12 electronic device workpiece processing apparatus. The chuck and
13 intermediate member are configured to communicate the process signals
14 intermediate the sensor and the data gathering device.

15 According to another aspect of the invention, an electronic device
16 workpiece processing apparatus includes a workpiece holder. Exemplary
17 workpiece holders include a chuck and an intermediate member. The
18 workpiece holder is adapted to receive an electronic device workpiece
19 and includes an electrical coupling configured to electrically couple with
20 an electrical coupling of a received electronic device workpiece. The
21 workpiece holder is adapted for communication of signals between the
22 electronic device workpiece and the workpiece holder.

23 The present invention also provides methods of communicating
24 signals within an electronic device workpiece processing apparatus.

1 According to one method, a workpiece holder is coupled with an
2 electronic device workpiece and a signal can be communicated through
3 the workpiece holder. The communicated signals preferably contain
4 process information.

5 Another aspect of the invention provides a method comprising
6 electrically coupling a sensor of an electronic device workpiece with a
7 workpiece holder configured to receive the workpiece. The workpiece
8 holder is configured to communicate signals generated using the sensor.

9 Yet another aspect of the present invention provides a method
10 comprising communicating signals intermediate circuitry of an electronic
11 device workpiece and circuitry of a workpiece holder configured to
12 receive the electronic device workpiece.

13 BRIEF DESCRIPTION OF THE DRAWINGS

14 Preferred embodiments of the invention are described below with
15 reference to the following accompanying drawings.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

This disclosure of the invention is submitted in furtherance of the constitutional purposes of the U.S. Patent Laws "to promote the progress of science and useful arts" (Article 1, Section 8).

Referring to Fig. 1, an embodiment of an electronic device workpiece processing apparatus 10 is illustrated. The depicted apparatus 10 includes a workpiece holder 12 adapted to couple with or

1 receive an electronic device workpiece 20. Exemplary workpiece
2 holders 12 include a chuck 40 as shown in Fig. 1 and an intermediate
3 member described below. Exemplary electronic device workpieces
4 include calibration workpieces and production workpieces.

5 Workpiece holder 12 includes an electrical coupling (not illustrated
6 in Fig. 1) configured to electrically connect with an electrical coupling
7 of electronic device workpiece 20. Connection of circuitry including
8 electrical couplings of electronic device workpiece 20 and workpiece
9 holder 12 permits communication of signals between electronic device
10 workpiece 20 and workpiece holder 12. Workpiece holder 12 is
11 configured to receive and conduct or communicate signals.

12 Electronic device workpiece 20 comprises a calibration workpiece
13 in the presently described embodiment. Production workpieces typically
14 undergo processing from which subsequent devices are formed.
15 Exemplary production electronic device workpieces include semiconductor
16 wafers, glass or quartz substrates for flat panel or field emission display
17 devices, etc. Typical production workpieces are processed and
18 subsequently utilized to form products used in a variety of electronic
19 devices. Calibration and production electronic device workpieces can
20 comprise silicon, glass, quartz or other materials.

21 Workpiece holder 12 can be implemented in various configurations.
22 In the embodiment depicted in Fig. 1, workpiece holder 12 is
23 implemented as a chuck 40. Chuck 40 is configured to receive
24

1 electronic device workpiece 20 and preferably compatible with processing
2 of electronic device workpiece 20.

3 In the depicted embodiment, electronic device workpiece 20
4 comprises a calibration workpiece. Workpiece 20 includes opposing
5 surfaces 21, 22 (only surface 21 is shown in Fig. 1). A plurality of
6 sensors 23 are borne by or provided adjacent first surface 21 of
7 workpiece 20. Sensors 23 are configured to sense a process condition
8 within apparatus 10 and generate and output process signals
9 corresponding to the sensing. Exemplary process signals contain
10 information regarding processing of a workpiece.

11 The depicted sensors 23 comprise resistance temperature devices
12 (RTD). The information within the process signals can comprise
13 temperature information corresponding to sensed temperatures at plural
14 positions across surface 21 of workpiece 20.

15 In a preferred embodiment, sensors 23 comprising resistance
16 temperature devices individually include plural electrical connections.
17 Such resistance temperature devices include four electrical connections
18 providing two connections for voltage monitoring and two connections
19 for current monitoring. This configuration provides cancellation or
20 minimization of wire resistances of connections to sensors 23.

21 In the embodiment depicted in Fig. 1, chuck 40 is coupled with
22 a data gathering device or data recorder 14. Data gathering device 14
23 is configured to couple with an electrical interconnect of chuck 40 and
24 receive process signals through chuck 40 outputted from plural

1 sensors 23 provided upon workpiece 20. One embodiment of data
2 gathering device 14 comprises a ClientPro MTR computer available from
3 Micron Electronics, Inc. utilizing a Pentium™ processor.

4 Data gathering device 14 is configured to receive and process
5 signals provided by sensors 23 and corresponding to processing
6 conditions of workpiece 21. Alterations to processing conditions of
7 apparatus 10 can be changed responsive to reception of process signals
8 within device 14.

9 Electronic device workpiece 20 is held by chuck 40 with the use
10 of a vacuum or mechanical coupling in exemplary embodiments. The
11 depicted chuck 40 includes a lip 52 configured to receive and maintain
12 electronic workpiece device 20 in a desired position relative to
13 chuck 40.

14 Referring to Fig. 2, the depicted chuck 40 includes a surface 39
15 and an opposing surface 41. Chuck 40 also includes circuitry
16 comprising a plurality of electrical interconnects 44 and plural electrical
17 couplings 45 adjacent surface 41. Electrical interconnects 44 are
18 configured to connect with or include respective electrical couplings 45
19 of chuck 40. In addition, electrical interconnects 44 are configured to
20 conduct or communicate signals within and through chuck 40. In the
21 depicted embodiment, electrical interconnects 44 are configured to
22 conduct or communicate signals intermediate surfaces 39, 41 of
23 chuck 40.
24

1 The depicted electrical interconnects 44 comprise pogo pins which
2 are available from Rika Denshi America, Inc. and have product
3 designation RM-500 Series. Electrical interconnects 44 of other
4 configurations can be utilized.

5 Calibration workpiece 20 is shown received within chuck 40 in
6 Fig. 2. Lip 52 is operable to define a compartment for reception of
7 electronic device workpiece 20. Surfaces 21, 22 of electronic device
8 workpiece 20 are illustrated in Fig. 2. A plurality of sensors 23, such
9 as resistance temperature devices, are shown provided or fabricated upon
10 surface 21 of electronic device workpiece 20. In the depicted
11 embodiment, an insulative protective layer 28 is shown formed over
12 sensors 23. Layer 28 can comprise glass or other suitable material for
13 protecting sensors 23.

14 One exemplary electronic device workpiece 20 is described in the
15 patent application having Serial No. 09/032,184, filed February 27, 1998,
16 and cited above. Such a workpiece 20 includes circuitry comprising
17 electrical couplings 24, vias 25 and connections 27 corresponding to
18 respective sensors 23.

19 Connections 27 comprise conductive traces in the described
20 embodiment and are configured to couple sensors 23 with respective
21 vias 25. Vias 25 extend intermediate surfaces 21, 22 of electronic
22 device workpiece 20. Vias 25 preferably include a conductive material
23 to electrically couple surfaces 21, 22 of workpiece 20. In a preferred
24 embodiment, the conductive material in vias 25 is electrically isolated

1 from electronic workpiece 20. For example, an insulator or dielectric
2 layer around the via conductor can be utilized.

3 Electrical couplings 24 are adjacent or borne by surface 22 of
4 electronic device workpiece 20. Electrical couplings 24 comprise bond
5 or land pads of electronic device workpiece 20 and correspond to
6 respective sensors 23 and vias 25. Further, electrical couplings 24 are
7 preferably configured to provide electrical connection of sensors 23 with
8 electrical couplings of chuck 40 and an intermediate member (if
9 provided) as described below.

10 Electrical couplings 45 are spring loaded and configured to
11 protrude slightly above surface 41 of chuck 40. Electrical couplings 45
12 of chuck 40 are configured or adapted to couple with electrical
13 couplings 24 of electronic device workpiece 20. Positioning or reception
14 of electronic device workpiece 20 upon chuck 40 slightly depresses
15 electrical couplings 45 of pogo pins or electrical interconnects 44 in the
16 described embodiment. Electrical connection is established intermediate
17 electrical couplings 24 of device 20 and electrical couplings 45 of
18 chuck 40.

19 Following connection of electrical couplings 24, 45, process signals
20 from data gathering device 14 can be applied to sensors 23 via wire 13,
21 electrical interconnect 44, electrical couplings 24, 45 and
22 connections 25, 27. In addition, signals outputted from sensors 23 can
23 be conducted via connections 25, 27, electrical couplings 24, 45,
24 electrical interconnect 44, and wire 13 to data gathering device 14.

1 The depicted pogo pins are configured to remain within chuck 40 during
2 normal production use or processing of production electronic device
3 workpieces in one embodiment of the invention.

4 Workpiece holder 12, as depicted in Fig. 2, includes a plurality
5 of vacuum channels or chambers 49 extending intermediate
6 surfaces 39, 41. Vacuum chambers 49 are coupled with a vacuum
7 source 51 in a preferred embodiment. Vacuum chambers 49 are
8 configured to receive a vacuum to couple a received electronic device
9 workpiece 20 with workpiece holder 12. Mechanical devices such as
10 clamps are utilized in other embodiments to attach or couple
11 workpiece 20 with workpiece holder 12.

12 Following coupling of the circuitry of calibration workpiece 20 with
13 the circuitry of workpiece holder 12, process signals can be
14 communicated intermediate sensors 23 and data gathering device 14.
15 Thereafter, the coupling of respective circuitry of workpiece 20 and
16 workpiece holder 12 can be broken and another calibration workpiece
17 or production workpiece can be coupled with workpiece holder 12.

18 Referring to Fig. 3, an alternative embodiment of electronic device
19 workpiece processing apparatus 10 is illustrated. The depicted
20 processing apparatus 10 includes a workpiece holder 12 comprising an
21 insert or intermediate member 60. Intermediate member 60 is also
22 referred to as an insert or interposer. The depicted intermediate
23 member 60 is adapted to couple with chuck 40, and receive and couple
24 with electronic device workpiece 20. Intermediate member 60 is

1 preferably configured to communicate signals intermediate chuck 40 and
2 electronic device workpiece 20.

3 Intermediate member 60 preferably comprises a nonconductive
4 material which is compatible with a fabrication environment.
5 Intermediate member 60 includes opposing surfaces 61, 62 and circuitry
6 comprising at least one electrical interconnect 64 and plural electrical
7 couplings 65, 66. Electrical interconnect 64 is configured to electrically
8 couple opposing surfaces 61, 62 of intermediate member 60. In
9 addition, electrical interconnect 64 is configured to couple circuitry of
10 workpiece 20 and circuitry of chuck 40. Surface 61 of intermediate
11 member 60 is configured to face a received electronic device
12 workpiece 20. Surface 62 of intermediate member 60 is configured to
13 face chuck 40 during processing of electronic device workpieces 20.

14 Intermediate member 60 is configured to receive electronic device
15 workpiece 20 having electrical couplings 24. In addition, intermediate
16 member 60 is configured to couple with chuck 40 having electrical
17 couplings 45. Electrical interconnects 64 are configured to electrically
18 connect electrical couplings 24 of electronic device workpiece 20 with
19 electrical couplings 45 of chuck 40. The depicted electrical
20 interconnects 64 comprise double-ended probes or pogo pins which are
21 also available from Rika Denshi America, Inc. and have product
22 designation B1052 Series Probes. Other suitable probes include
23 B1080-C3 Low Profile Probes and the B1303-C3 or B1316-C3 Ball Grid
24 Probes. Electrical interconnects 64 of other configurations can be utilized.

1 The depicted intermediate member includes a lip 63 configured to
2 receive electronic device workpiece 20. Chuck 40 includes lip 52
3 configured to receive intermediate member 60.

4 In the depicted embodiment, mechanical devices such as clamps
5 can be utilized to couple or maintain electronic device workpiece 20
6 with surface 61 of intermediate member 60. Further, a vacuum is
7 utilized in the illustrated embodiment to couple intermediate member 60
8 with chuck 40. The depicted chuck 40 includes plural chuck vacuum
9 channels or chambers 49. Vacuum channels 49 are in fluid
10 communication with openings 53 at surface 41 of chuck 40. Vacuum
11 channels or chambers 49 are configured to couple with a vacuum
12 source 51 and receive a vacuum to couple intermediate member 60
13 relative to chuck 40. In other embodiments, intermediate member 60
14 is received and maintained within chuck 40 by mechanical fasteners such
15 as clamps. In addition, a vacuum can be utilized in other arrangements
16 to couple workpiece 20 with intermediate member 60.

17 An alternative configuration of intermediate member 60 includes
18 utilization of a copper film/polyamide tape having conductive microbumps
19 to provide electrical connection of sensors 23 and electrical couplings 45
20 of chuck 40. An exemplary tape is available from Nitto Denko
21 America, Inc.

22 Referring to Figs. 3 and 4, the depicted chuck 40 includes a
23 plurality of electrical couplings 45. Electrical couplings 45 are embodied
24 as pogo plugs 47 in the presently described embodiment. The depicted

1 pogo plugs 47 individually include an insulator 50 provided about
2 conductive electrical coupling 45. Exemplary materials of insulator 50
3 include plastic, glass, ceramic, Teflon, and Torlon. Pogo plugs 47 can
4 be provided within a plurality of vias 48 formed within chuck 40.
5 Wires 13 are connected with electrical couplings 45 of pogo plugs 47
6 and data gathering device 14.

7 Referring to Fig. 5, details of chuck 40 are illustrated. Electrical
8 couplings 45 are shown adjacent surface 41 of chuck 40. Insulators 50
9 of pogo plugs 47 are shown to isolate conductive electrical couplings 45
10 from chuck 40. In addition, openings 53 of vacuum channels or
11 chambers 49 are visible within surface 41. Lip 52 surrounds the
12 periphery of chuck 40 in the illustrated embodiment and is configured
13 to receive intermediate member 60 as previously described.

14 Referring again to Fig. 3, reception of electronic device
15 workpiece 20 upon surface 61 of intermediate member 60 slightly
16 depresses electrical couplings 65 of pogo pins 64 establishing an
17 electrical connection intermediate electrical couplings 24, 65. Similarly,
18 placement of intermediate member 60 within chuck 40 slightly depresses
19 electrical couplings 66 of pogo pins 64 establishing electrical conduction
20 intermediate electrical couplings 45, 66.

21 In the described embodiment, intermediate member 60 is
22 configured to temporarily receive electronic device workpiece 20.
23 Following processing of electronic device workpiece 20, workpiece 20 can
24 be removed from intermediate member 60. Also, chuck 40 is

1 configured to temporarily receive intermediate member 60 in the
2 described embodiment. Following production or processing of electronic
3 device workpieces 20, intermediate member 60 can be removed from
4 chuck 40.

5 One advantage of the embodiment described with reference to
6 Fig. 3, is the provision of a clean production chuck 40 having no
7 moving parts. In addition, chuck 40 is isolated to a greater extent
8 from the processing environment utilized to fabricate or process
9 electronic device workpieces 20. Utilization of intermediate member 60
10 provides processing of electronic device workpiece 20 apart from
11 chuck 40. Such minimizes exposure of chuck 40 to processing materials
12 utilized during fabrication processes.

13 According to one processing methodology, calibration workpiece 20
14 is received within intermediate member 60, and intermediate member 60
15 placed upon chuck 40. Following sensing of process conditions using
16 sensors 23, calibration workpiece 20 is removed from intermediate
17 member 60. Thereafter, production electronic device workpieces are
18 individually placed within intermediate member 60 and processing of
19 such workpieces occurs in mass.

20 Referring to Fig. 6, another embodiment of an electronic
21 workpiece processing apparatus 10 according to the present invention is
22 illustrated. Workpiece holder 12 depicted in Fig. 6 comprises a
23 chuck 40 configured to receive plural electronic device workpieces. In
24 particular, chuck 40 is configured to receive a calibration workpiece 20

1 and a production workpiece 80. Lip 52 of chuck 40 has been vertically
2 extended in the embodiment illustrated in Fig. 6 to accommodate
3 reception of plural electronic device workpieces. Utilization of the
4 configuration of apparatus 10 of Fig. 6 enables processing of production
5 workpieces 80 while monitoring processing conditions using calibration
6 workpiece 20.

7 Calibration workpiece 20 includes plural sensors 23 and
8 corresponding connections 25, 27 and electrical coupling 24 although only
9 one construction is labelled as such in Fig. 6. The calibration
10 workpiece 20 illustrated in Fig. 6 additionally includes plural through
11 holes or vacuum chambers 26 passing intermediate surfaces 21, 22.
12 Plural through holes 26 are preferably provided within calibration
13 workpiece 20 although only one such through hole is illustrated in
14 Fig. 6.

15 The depicted chuck 40 comprises plural vacuum channels or
16 chambers 49, 55 intermediate surfaces 39, 41 of chuck 40. Vacuum
17 channels or chambers 49 allow application of a vacuum to calibration
18 workpiece 20 which pulls calibration workpiece 20 toward chuck 40.
19 Vacuum chambers 55 and through holes 26 permit application of a
20 vacuum to production workpiece 80 which pulls production workpiece 80
21 toward calibration workpiece 20 and chuck 40.

22 In particular, vacuum channels or chambers 49, 55 are configured
23 to couple with an external vacuum source 51 at positions adjacent
24 surface 39 of chuck 40. Vacuum source 51 is configured to provide a

1 calibration wafer hold-down vacuum to chamber 54 using a supply
2 line 56. In addition, the illustrated vacuum source 51 is configured to
3 provide a production wafer hold-down vacuum to vacuum channel or
4 chambers 26, 55 and production wafer 80 via connection 57. As
5 illustrated, through holes 26 of calibration wafer 20 are configured to
6 align with vacuum chambers 55 of chuck 40. Application of hold-down
7 vacuums to channels or chambers 26, 49, 55 operate to couple the
8 respective calibration workpiece 20 and production workpiece 80 with
9 chuck 40.

10 In an alternative embodiment, mechanical devices are utilized to
11 couple calibration workpiece 20 and production workpiece 80 with
12 chuck 40.

13 The depicted chuck 40 includes an electrical interconnect 44 and
14 an electrical coupling 45 configured to meet or couple with electrical
15 coupling 24 of calibration workpiece 20. In the depicted arrangement,
16 electrical interconnect 44 comprises a pogo pin. Wire connection 13
17 operates to couple electrical interconnect 44 with data gathering
18 device 14. In the depicted embodiment, electrical interconnect 44
19 comprises circuitry configured to conduct process signals within chuck 40
20 and intermediate surfaces 39, 41. Data gathering device 14 is
21 configured to receive the process signals from sensors 23 through
22 chuck 40 and intermediate member 60.

23 Referring to Fig. 7, an exemplary portion of a calibration
24 workpiece 20 is illustrated. Sensor 23 comprising a resistance

1 temperature device is shown provided upon surface 21 of calibration
2 workpiece 20. Via 25 is formed within calibration workpiece 20
3 intermediate surfaces 21, 22. Via 25 is conductive to permit
4 communication of process signals. Electrical connection 27 is illustrated
5 connecting sensor 23 and via 25. In the depicted embodiment, electrical
6 connection 27 comprises a conductive trace.

7 An insulative dielectric layer 30 is provided about via
8 conductor 25 in some configurations. Provision of dielectric layer 30
9 is preferred if workpiece 20 is semiconductive or conductive. Layer 30
10 is typically not utilized if workpiece 20 comprises a non-conductive
11 material, such as glass.

12 In the preferred embodiment, a conformal protection layer 28 is
13 provided over surface 21, sensor 23 and connection 27. Layer 28
14 operates to protect surface 21, sensor 23 and electrical connection 27
15 from the processing environment including gasses, chemicals, plasmas, etc.
16 utilized during processing of the electronic device workpieces. In the
17 described embodiment, layer 28 comprises glass. The glass may be
18 sputtered over calibration workpiece 20 including sensors 23, electrical
19 connections 27 and surface 21.

20 Referring to Fig. 8, a thick protection layer 28 is shown provided
21 over sensors 23 and electrical connection 27. Layer 28 is preferably
22 chemically or mechanically polished providing a flat or smooth
23 surface 29 of layer 28. A polished or flat smooth surface 29 of
24 layer 28 facilitates vacuum sealing of a production workpiece 80 placed

1 over calibration workpiece 20. In addition, flat smooth surface 29
2 provides enhanced wearing properties during processing of production
3 workpieces 80 or exposure of calibration workpiece 20 to process
4 conditions. A worn or damaged glass layer 28 may be reprocessed to
5 add more glass or resurfaced to remove defects within the existing glass
6 layer.

7 Referring to Fig. 9, a portion of another embodiment of chuck 40
8 configured to receive a calibration workpiece (not illustrated in Fig. 9)
9 is depicted. Through hole 42 is shown passing intermediate
10 surfaces 39, 41 of chuck 40. Plural through holes 42 are preferably
11 provided in chuck 40 although only one such through hole is illustrated
12 in Fig. 9. An insulative layer (not illustrated in Fig. 9) is preferably
13 provided if chuck 40 comprises a conductive material. In particular, an
14 insulative layer can be provided about interconnect 44 or along the
15 surface of through hole 42 to electrically isolate interconnect 44 from
16 chuck 40. Such an insulative layer is not typically utilized if chuck 40
17 is non-conductive.

18 Electrical interconnect 44 comprises a conductive column or wire
19 in the embodiment depicted in Fig. 9. In particular, the depicted
20 electrical interconnect 44 comprises a buckle beam or column wire
21 contact. Electrical interconnect 44 is provided within through hole or
22 via 42. Electrical interconnect 44 includes electrical couplings 45, 46
23 which are configured to extend outward from respective surfaces 39, 41
24

1 of chuck 40 as shown. Column electrical interconnect 44 is configured
2 to provide electrical coupling with sensors 23.

3 A contact plate 90 is shown adjacent chuck 40 in Fig. 9.
4 Contact plate 90 includes circuitry 95 configured to provide electrical
5 connection with electrical couplings 46 of chuck 40. Contact plate 90
6 includes a land pad or electrical coupling 94 configured for electrical
7 connection with electrical coupling 46 of column interconnect 44.
8 Electrical contact plate 90 can comprise a printed circuit board (PCB),
9 ceramic thick/thin film circuit board in exemplary embodiments.
10 Circuitry 95 provides electrical connection intermediate surfaces 91, 96
11 of contact plate 90. Circuitry 95 is coupled with connection 13 and
12 data gathering device 14.

13 Referring to Fig. 10, an electronic device workpiece comprising a
14 calibration wafer 20 is shown contacting surface 41 of chuck 40. In
15 addition, chuck 40 is shown contacting contact plate 90. As illustrated,
16 placement of calibration workpiece 20 upon chuck 40 and chuck 40
17 upon plate 90 deflects conductive column 44. In particular, the original
18 position P of conductive column 44 is represented by a dashed line in
19 Fig. 10. Placement of calibration workpiece 20 upon chuck 40 and
20 chuck 40 upon contact plate 90 results in deflection of conductive
21 column 44 to the illustrated position P' in Fig. 10.

22 In the illustration of Fig. 10, electrical couplings 45, 46 are
23 provided in a conductive relationship with respective electrical
24 couplings 24, 94 of calibration workpiece 20 and contact plate 90

1 respectively. Through hole 84 is preferably sized to provide electrical
2 isolation of conductive column interconnect 44 from chuck 40 when
3 conductive column 44 is deflected as shown in Fig. 10. In particular,
4 chuck 40 can comprise a material 43 which is conductive in some
5 embodiments. Spacing conductive column 44 from material 43 of
6 chuck 40 provides electrical insulation or isolation of process signals
7 passing through conductive column electrical interconnect 44 from
8 chuck 40.

9 In another embodiment, conductive wire interconnect 44 is fixed
10 via electrical coupling 46 to electrical coupling 94 of contact plate 90.
11 Electrical coupling 45 of conductive column 44 can thereafter be free
12 to couple with electrical coupling 24 of calibration workpiece 20.

13 Referring to Fig. 11, another configuration having conductive
14 column 44 fixed to chuck 40 at an intermediate location of through
15 hole 84 is illustrated. Both ends of conductive column 44 comprise
16 respective electrical couplings 45, 46 configured to move or deflect
17 responsive to coupling with external pads or electrical couplings. In the
18 depicted embodiment, a securing device 88 is formed within through
19 hole 84 to fix conductive column 44 at the approximately middle portion
20 of through hole 84. In exemplary embodiments, securing device 88
21 comprises epoxy press fit as a disk or plug into through hole 84. In
22 another embodiment, through hole 84 is filled with epoxy which is
23 subsequently machined to form securing device 88. Securing device 88
24 is preferably non-conductive if chuck 40 comprises a conductive material.

1 Referring to Fig. 12, an alternative configuration is shown
2 providing an encapsulated conductive column wire 44 within through
3 hole 84. An electrically insulating encapsulating material 97, such as
4 an elastomer, can be utilized to encapsulate conductive column 44.
5 Such is preferred wherein chuck 40 comprises a conductive material 43.
6 Encapsulation of conductive column interconnect 44 is utilized to hold
7 conductive column wire 44 within through hole 84 and isolate conductive
8 column 44 from chuck 40. Utilization of an encapsulating material 97
9 encloses through hole 84 of chuck 40 thereby reducing exposure of
10 chuck 40 to contaminating materials present during processing of
11 electronic device workpieces by apparatus 10.

12 Other electrical connections can be utilized within chuck 40 and
13 intermediate member 60 of electronic workpiece device processing
14 apparatus 10 in other embodiments. Exemplary connections include
15 Short Contact™ connections available from Johnstech International
16 Corporation and conventional socket type contacts (e.g., spring fingers).
17 Other useable contacts include coil spring, leaf spring and probe needle
18 type contacts and contacts available from Interconnect Devices, Inc.
19 Microspring™ contacts available from FormFactor, Inc. may also be
20 utilized. Other exemplary contacts or pins are described in U.S. Patent
21 No. 5,495,667, incorporated herein by reference. Further, pins can be
22 placed upon land pads of an electronic device workpiece and configured
23 for mating receipt within sockets provided upon chuck 40 or
24 intermediate member 60 of apparatus 10.

1 In compliance with the statute, the invention has been described
2 in language more or less specific as to structural and methodical
3 features. It is to be understood, however, that the invention is not
4 limited to the specific features shown and described, since the means
5 herein disclosed comprise preferred forms of putting the invention into
6 effect. The invention is, therefore, claimed in any of its forms or
7 modifications within the proper scope of the appended claims
8 appropriately interpreted in accordance with the doctrine of equivalents.
